# The HIV Vaccines and Passive Immunization Pipeline Report 2023

By Richard Jefferys

The past few years have proven extremely consequential for the HIV vaccine field, with disappointing results from several efficacy trials necessitating a significant recalibration of the research agenda.

At the current time, there's only one type of immune response believed to be capable of achieving significant protection against acquisition of HIV, called a broadly neutralizing antibody (bNAb) response. The major challenge for vaccine development is that bNAbs are very rarely naturally induced in people living with HIV and no method has yet been developed for inducing them with vaccines (research is ongoing).

In the absence of an ability to create bNAbs with a vaccine, researchers were hoping that other types of immune responses—designated non-neutralizing responses—may be able to offer at least some level of efficacy for reducing the risk of acquiring HIV. The hope was bolstered by a large trial among people at relatively low risk of exposure to HIV in Thailand, [RV144](#), which in 2009 reported an approximately one-third reduction in the incidence of HIV infection associated with receipt of a non-neutralizing vaccine regimen. However, the result was at the borderline of statistical significance, leaving residual uncertainty as to the robustness of the findings.

After the RV144 results, the best near-term prospect for an HIV vaccine was considered to be the development of regimens that could at least duplicate and preferably improve upon the slight degree of efficacy that was reported. But three large, post-RV144 efficacy trials of vaccines that induce non-neutralizing responses have since been conducted and none were able to demonstrate a significant protective effect against HIV acquisition:

- HIV Vaccine Trials Network (HVTN) 702 took place in South Africa with a prime-boost vaccine regimen closely modeled on the components used in RV144. Results, [announced in February 2020](#), showed that the vaccines were ineffective at preventing HIV.
- Imbokodo was one of two efficacy trials jointly sponsored by HVTN and the vaccine manufacturer Janssen Vaccines & Prevention B.V., part of the Janssen Pharmaceutical Companies of Johnson & Johnson. The study assessed a prime-boost regimen with an adenovirus serotype 26 vector and HIV envelope protein boosts in a population of 2,637 cisgender women at high risk of exposure to HIV in Malawi, Mozambique, South Africa, Zambia, and Zimbabwe. Initial results, [disclosed on August 31, 2021](#), demonstrated no statistically significant efficacy but there was a slight, non-significant 25 percent lower HIV incidence among the vaccine recipients compared to the placebo (dummy vaccine) arm.

In a presentation at the International AIDS Conference in July 2022, the University of Washington statistician Avi Kenny revealed that there had been an error in the preliminary analysis and that the hint of a difference between the trial arms was essentially a mirage: in the revised analysis, HIV incidence was numerically around 14 percent lower in the vaccine arm, underscoring the absence of efficacy.

- The second and largest of the HVTN/Janssen HIV vaccine efficacy studies was Mosaico, which enrolled 3,887 cisgender men and transgender people who have sex with cisgender men and/or transgender people at sites in Argentina, Brazil, Italy, Mexico, Peru, Poland, Spain, and the United States. The vaccine regimen was very similar to that used in Imbokodo with just a small tweak in the design of the HIV envelope protein boost. On January 18 of this year, very disappointing news was released that the trial was being discontinued after an interim review by the Data Safety Monitoring Board (DSMB) found equivalent numbers of HIV acquisition events among vaccine and placebo recipients, precluding any possibility of efficacy. Details of the results were subsequently briefly presented by Dr. Susan Buchbinder at the 2023 Conference on Retroviruses and Opportunistic Infections (CROI): the vaccines proved safe, but the HIV incidence was the same in the vaccine and placebo arms of the trial (113 cases of HIV acquisition in each group, which included 1,938 and 1,940 evaluable participants, respectively — this equated to an HIV incidence of 4.1 per 100 person-years in both arms of the trial).

Based on current scientific knowledge, Mosaico is likely to represent the last large scale efficacy evaluation of a non-neutralizing approach to HIV vaccination for the foreseeable future. Although the vaccines didn't work as hoped, the information collected in these trials may still provide important information to researchers. Mosaico remains in active follow up but has been removed from our pipeline table because the vaccine regimen will not be developed further.

One smaller phase IIb efficacy trial remains ongoing: PrEPVacc, which employs a novel design to assess whether non-neutralizing HIV vaccine regimens can add significantly to the protection obtained by oral pre-exposure prophylaxis (PrEP) with either Truvada or Descovy. The statistical parameters of the study are such that it can only detect vaccine efficacy of 70 percent or greater. The likelihood of success appears low, and results should become available within the next few years.

Dr. Lawrence Corey, head of the HVTN, spoke at CROI to outline the revised priorities of the HIV vaccine field after Mosaico. Work has been underway for several years to solve the daunting obstacles to inducing bNAbs with vaccines, and this research now takes center stage. Corey noted that vaccines that induce other types of non-neutralizing responses such as T-cell responses will continue to be investigated but will almost certainly need to be part of a combination approach that includes bNAbs.

Corey also highlighted several key obstacles HIV presents to traditional vaccination methods, with the virus having evolved multiple mechanisms for resisting antibody-mediated neutralization. The virus's outer envelope protein is enshrouded by glycan (sugar) molecules that most antibodies cannot penetrate. The HIV envelope is highly mutable, with few regions of the protein representing stable, conserved antibody targets. Lastly, envelope protein spikes are sparsely distributed on HIV's surface (in Corey's description, "a bald virus"), making them more difficult for antibodies to target.

Reflecting the new landscape, most new HIV vaccine trials added since the 2022 Pipeline Report aim to inform efforts to develop approaches capable of generating bNAb responses. In some cases, versions of the HIV envelope protein designed to mimic the natural three-pronged (trimeric) structure more closely are being evaluated.

Results from the first-in-human trial of an HIV envelope protein trimer, Trimer 4571, were published in the journal *eClinicalMedicine* in June 2022. Administration with alum proved safe, with transient injection site reactions the primary side effect. The researchers found that resulting antibody responses tended to be directed at a region at the base of the envelope that doesn't lead to virus neutralization, providing information to help refine candidate envelope trimers with the aim of inducing antibodies against better targets. For example, the recently launched HVTN 303 trial is investigating a fusion protein designed to steer immune responses away from the envelope trimer base (see table).

Another leading strategy, called germline targeting, involves administering specially engineered proteins intended to increase the number of B cells with the genetic properties believed to be necessary for ultimately producing bNAbs.

Results from a phase I study using a protein construct named eOD-GT8 (short for engineered outer domain germline targeting version 8), published in December 2022, documented the successful expansion of the desired type of B cell: at baseline, the cells were detected in only 5 of 36 study participants, but this increased to 35 of 36 (97 percent) after administration of eOD-GT8. A secondary analysis also showed the induction of CD4+ T-cell responses, which are needed to help support antibody production by B cells. However, it's important to appreciate that additional – yet to be designed – immunization strategies will be needed to guide the B cells further down the pathway to bNAb production. In this initial study, eOD-GT8 was delivered as a protein with an immune-stimulating adjuvant, but newer ongoing trials are assessing whether mRNA technology can be used to speed the evaluation of this and similar constructs.

A vaccine being developed by Vir Biotechnology that is based on a weakened version of cytomegalovirus (CMV) is considered a promising candidate for inducing T-cell responses against HIV, based on results in the macaque model of SIV infection. A phase I trial of a prototype version codenamed VIR-1111 has been completed and no safety signals emerged but, according to a financial report from the company in November 2022, sustained HIV-specific T-cell responses have not been observed in recipients of lower doses (analyses of responses to higher doses have yet to be presented). The company is now launching a trial of VIR-1388, an updated version of the vaccine, in collaboration with the Bill and Melinda Gates Foundation and HVTN (see table).

Investigations continue into whether passive immunization might represent an alternative means of achieving protection against HIV with bNABs. Instead of vaccine-mediated induction, passive immunization directly administers bNABs that have been isolated from people with HIV and manufactured at scale, either by intravenous infusion or subcutaneous injection. Almost all the bNABs currently being studied have been modified into long-acting versions to allow for less frequent dosing (bNABs with this modification have LS appended to their name).

The potential for bNABs to protect against HIV acquisition has been demonstrated by the AMP trials, which found that intravenous infusion of VRC01 – one of the first bNABs to be discovered – significantly lessened the risk of HIV acquisition among a subset of participants exposed to viral variants sensitive to neutralization by the antibody. The results have provided critical information on the levels of bNAB required to achieve protection against HIV while also emphasizing that the variability of circulating viruses will need to be addressed by using combinations of different bNABs or antibody constructs engineered to inhibit multiple targets on the viral envelope (referred to as bispecific or trispecific bNABs).

The largest current passive immunization study is CAPRISA 012C, the third in an iterative series of trials primarily focused on two long-acting bNABs, CAP256V2LS and VRC07-523LS. The phase II trial will assess subcutaneous dosing of the combination either every four or every six months, compared to placebo, in over 900 cisgender women in South Africa aged 18–30.

Results from a smaller phase I trial, CAPRISA 012B, were published in *The Lancet* in April 2023. The study enrolled 42 cisgender women in South Africa and compared intravenous and subcutaneous administration of the bNABs. Subcutaneous delivery was accomplished via a pump together with recombinant human hyaluronidase (trade name ENHANZE), which allows for administration of larger volumes of bNAB by temporarily alleviating a protein barrier present under the skin (see video animation of the mechanism). The time required for the subcutaneous pump was brief, with the maximum being 18 minutes.

The researchers report that the two bNABs were generally well tolerated and showed favorable pharmacokinetic parameters, leading to the launch of CAPRISA 012C. The most serious side effect was a transient loss of white blood cells (lymphopenia), which recovered within days. The data relating to this adverse event was reviewed by specialists and adjudged not to be a health concern; the study authors note that it's unclear if other bNABs may have similar effects because previous studies typically haven't assessed blood values the day after dosing.

Recombinant human hyaluronidase was also evaluated in a phase I study of the bNAB N6LS. Results were presented at CROI 2023, with the researchers concluding that the approach is safe and has potential to offer a viable alternative to intravenous infusion. The main side effect was erythema (reddening of the skin) around the injection site, which was of greater severity among recipients of the higher of the two bNAB doses that were assessed. Severe erythema wasn't associated with the use of recombinant

human hyaluronidase in the CAPRISA 012B trial, and this difference may deserve further analysis to understand if the absence was related to other factors such as the administration technique, the population, or the different bNABs that were given.

Only one other new bNAB trial has been registered over the past year, a phase I investigation of VRC01.23LS delivered intravenously or subcutaneously. The bNAB is the product of a structure-based strategy for improving the potency of the parental antibody, VRC01. Preclinical laboratory studies of VRC01.23LS have demonstrated an approximately 10-fold greater potency (meaning superior inhibition of HIV at lower concentrations).

HVTN is now working toward an efficacy trial like the AMP studies but using a triple bNAB combination. While it's still unclear if passive immunization could become an effective, affordable, and practical HIV prevention option, the research also has the potential to shed additional light on the magnitude and diversity of bNAB responses that an HIV vaccine would need to induce to achieve efficacy.

<ul style="list-style-type: none"> <li>Kwon YD, Asokan M, Gorman J, et al. A matrix of structure-based designs yields improved VRC01-class antibodies for HIV-1 therapy and prevention. <i>MAbs</i>. 2021 Jan-Dec;13(1):1946918.</li> </ul>				

Shaded entries represent additions since the 2022 Pipeline Report.

## Abbreviations

**Ad4:** adenovirus serotype 4

**bNAbs:** broadly neutralizing antibody

**CMDR:** Chiang Mai double recombinant

**CROI:** Conference on Retroviruses and Opportunistic Infections

**DREP:** alphavirus DNA-launched replicon

**GLA-SE:** glucopyranosyl lipid adjuvant formulated in a stable emulsion

**HVTN:** HIV Vaccine Trials Network

**IAVI:** International AIDS Vaccine Initiative

**LA:** long-acting

**mAb:** monoclonal antibody

**MHRP:** U.S. Military HIV Research Program

**MPLA:** monophosphoryl lipid A

**MVA:** modified vaccinia Ankara strain

**NIAID:** U.S. National Institute of Allergy and Infectious Diseases

**NIH:** U.S. National Institutes of Health

**PrEP:** pre-exposure prophylaxis

**R4P:** HIV Research for Prevention Conference

**TLR:** toll-like receptor

**UFO:** uncleaved pre-fusion optimized

**UVRI:** Uganda Virus Research Institute

**VRC:** The Dale and Betty Bumpers Vaccine Research Center
